(57) **ABSTRACT**

A method of processing a substrate is disclosed herein. The method includes applying a photoresist layer comprising a photoacid generator to a substrate, wherein a first portion of the photoresist layer has been exposed unprotected by a photomask to a radiation light in a lithographic exposure process. The method also includes applying an electric field to alter movement of photoacid generated from the photoacid generator substantially in a vertical direction, wherein the electric field is applied by a first alternating pair of a positive voltage electrode and a negative voltage electrode and a second alternating pair of a positive voltage electrode and a negative voltage electrode.

TOOLING CONFIGURATION FOR ELECTRIC/MAGNETIC FIELD GUIDED ACID PROFILE CONTROL IN A PHOTORESIST LAYER

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the priority benefit of U.S. provisional patent application Ser. No. 62/064,456, filed Oct. 15, 2014 and titled "Tooling Configuration for Electric/Magnetic Field Guided Acid Profile Control in a Photoresist Layer." The subject matter of this related application is hereby incorporated herein by reference.

BACKGROUND

Field

The present disclosure generally relates to methods and apparatuses for processing a substrate, and more specifically to methods and apparatuses for controlling photoresist line edge/width roughness.

Description of the Related Art

Integrated circuits have evolved into complex devices that can include millions of components (e.g., transistors, capacitors and resistors) on a single chip. Photolithography may be used to form components on a chip. Generally the process of photolithography involves a few basic stages. Initially, a photoresist layer is formed on a substrate. The photoresist layer may be formed by, for example, spin-coating. A chemically amplified photoresist may include a resist resin and a photoacid generator. The photoacid generator, upon exposure to electromagnetic radiation in the subsequent exposure stage, alters the solubility of the photoresist in the development process. The electromagnetic radiation may have any suitable wavelength, such as a wavelength in the extreme ultra violet region. The electromagnetic radiation may be from any suitable source, such as, for example, a 193 nm ArF laser, an electron beam, an ion beam, or other source. Excess solvent may then be removed in a pre-exposure bake process.

In an exposure stage, a photomask or reticle may be used to selectively expose certain regions of a photoresist layer disposed on the substrate to electromagnetic radiation. Other exposure methods may be maskless exposure methods. Exposure to light may decompose the photoacid generator, which generates acid and results in a latent acid image (defined at least in part by "latent image lines") in the resist resin. After exposure, the substrate may be heated in a post-exposure bake process. During the post-exposure bake process, the acid generated by the photoacid generator reacts with the resist resin in the photoresist layer, changing the solubility of the resist of the photoresist layer during the subsequent development process.

After the post-exposure bake, the substrate, and, particularly, the photoresist layer may be developed and rinsed. After development and rinsing, a patterned photoresist layer is then formed on the substrate, as shown in FIG. **1**. FIG. **1** depicts an exemplary top sectional view of the substrate **100** having the patterned photoresist layer **104** disposed on a target material **102** to be etched. Openings **106** are defined between the patterned photoresist layer **104**, after the development and rinse processes, exposing the underlying target material **102** for etching to transfer features onto the target material **102**. However, inaccurate control or low resolution of the lithography exposure process may result in the photoresist layer **104** having being formed with undesirable dimensions, such as unacceptable line width roughness (LWR) **108**. Furthermore, during the exposure process, acid generated from the photoacid generator may diffuse randomly, including into regions under the mask where such acid is not intended to be diffused. This unintended diffusion may create undesired wiggling and/or an undesired roughness profile **150** at the interface of the patterned photoresist layer **104** with the openings **106**. Large line width roughness (LWR) **108** and undesired wiggling profile **150** of the photoresist layer **104** may result in inaccurate feature transfer to the target material **102**, which may lead to device failure and/or yield loss.

Therefore, there is a need for a method and an apparatus to control line width roughness (LWR) so as to obtain a patterned photoresist layer with desired dimensions. There is also a need for a method and an apparatus to control and reduce line edge/width roughness.

SUMMARY

A method of processing a substrate is disclosed herein. The method includes applying a photoresist layer comprising a photoacid generator to a substrate, wherein a first portion of the photoresist layer has been exposed unprotected by a photomask to a radiation light in a lithographic exposure process. The method also includes applying an electric field to alter movement of photoacid generated from the photoacid generator substantially in a vertical (or parallel) direction, wherein the electric field is applied by a first alternating pair of a positive voltage electrode and a negative voltage electrode and a second alternating pair of a positive voltage electrode and a negative voltage electrode.

A processing chamber for processing a substrate is disclosed herein. The processing chamber includes a supporting assembly with a surface for supporting a substrate. The processing chamber also includes a first electrode assembly comprising a first antenna and a second antenna positioned above the surface of the supporting assembly. The processing chamber also includes a second electrode assembly comprising a third antenna and a fourth antenna positioned below the surface of the supporting assembly. The processing chamber also includes a first power source coupled to the first electrode assembly and configured to provide the first electrode assembly with a positive voltage. The processing chamber also includes a second power source coupled to the second electrode assembly and configured to provide the second electrode assembly with a negative voltage.

BRIEF DESCRIPTION OF THE DRAWINGS

So that the manner in which the above recited features of the present disclosure can be understood in detail, a more particular description of the disclosure, briefly summarized above, may be had by reference to embodiments, some of which are illustrated in the appended drawings. It is to be noted, however, that the appended drawings illustrate only typical embodiments of this disclosure and are therefore not to be considered limiting of its scope, for the disclosure may admit to other equally effective embodiments.

FIG. **1** depicts a top view of an exemplary structure of a patterned photoresist layer disposed on a substrate conventionally in the art;

FIG. **2** is a schematic cross-sectional view of an apparatus for applying an electric field to a substrate on which a photoresist layer is disposed during a post-exposure bake process, according to an example;

FIG. **3**A is a side view of pairs of antennas above and below a substrate that includes a photoresist layer, for applying an electric field to the photoresist layer during a post-exposure bake process, according to an example;

FIG. **3**B is a side view of stacked pairs of antennas for processing multiple substrates that include photoresist layers, according to an example;

FIG. **3**C is a top view of an electrode assembly that includes the antennas of FIG. **3**A, for applying an electric field to the photoresist layer during a post-exposure bake process, according to an example;

FIGS. **3**D-**3**F illustrate examples of substrate holders for reducing electric field distortion while an electric field is applied to the photoresist layer during a post-exposure bake process;

FIG. **4**A-**4**B depict an acid distribution control of a photoresist layer during an exposure process; and

FIG. **5** is a flow diagram of one method of controlling acid distribution of a photoresist layer during a post-exposure bake process.

To facilitate understanding, identical reference numerals have been used, wherever possible, to designate identical elements that are common to the Figures. Additionally, elements of one embodiment may be advantageously adapted for utilization in other embodiments described herein.

DETAILED DESCRIPTION

Methods and apparatuses for controlling line edge/width roughness in lines formed by photolithography are provided. The random diffusion of acid generated by a photoacid generator during a post-exposure bake procedure contributes to line edge/width roughness which may be mitigated utilizing the techniques disclosed herein. Methods disclosed herein apply an electric field to a substrate on which the photoresist layer is disposed during a post-exposure bake step of a photolithography processes. Application of the electric field as described herein controls the diffusion and distribution of the acids generated by the photoacid generator, preventing the line edge/width roughness that results from random diffusion. Apparatuses and methods for performing the above-mentioned techniques are disclosed herein.

FIG. **2** is a side view of one embodiment of a processing chamber **200** in which a post-exposure bake procedure may be performed with an electric field applied to a substrate **240** in accordance with one example. As described above, this post-exposure bake procedure is performed after an exposure stage of a photolithography process, in which a photoresist layer on the substrate **240** is exposed to electromagnetic radiation. More specifically, in the exposure stage a photoresist layer is formed on a substrate **240**. The photoresist may include a resist resin and a photoacid generator. A mask or other mechanism is used to selectively expose the photoresist layer to electromagnetic radiation. The mask causes a latent pattern to form in the photoresist layer, where the layout of the latent pattern is dependent on the layout of the mask. The latent pattern is characterized by a change in the chemical properties of the photoresist layer such that subsequent stages can selectively remove desired portions of the photoresist layer. The post-exposure bake process is performed after the exposure stage and consists of applying heat to the photoresist layer to cause further changes to the chemical properties of the photoresist layer such that a subsequent development stage will selectively remove the portions of the photoresist. The techniques disclosed herein include applying an electric field having a specified configuration during the post-exposure bake process such that a subsequent development stage will remove portions of the photoresist in way that edges at the interface between removed and unremoved portions of the photoresist remain smoother than if the electric field were not applied.

The substrate **240** on which the photoresist is disposed may be any type of substrate, such as a dielectric substrate, a glass substrate, a semiconductor substrate, or a conductive substrate. The substrate **240** may have a material layer **245** disposed thereon. The material layer **245** may be any desired layer. In other embodiments, the substrate **240** may have more than one material layer **245**. The substrate **240** also has the photoresist layer **250** disposed over the material layer **245**. When the post-exposure bake process is conducted, the substrate **240** has been previously exposed to electromagnetic radiation in an exposure stage of a photolithography process. The photoresist layer **250** thus has latent image lines **255**, which define a latent image of electromagnetically-altered photoresist, formed therein from the exposure stage. The latent image lines **255** may be substantially parallel to each other. In other embodiments, the some or none of latent image lines **255** may be substantially parallel to each other.

The processing chamber **200** includes a substrate support assembly **238** that includes a substrate automation system **215** with a belt **213**, moved via rollers **212**, for supporting and moving the substrate **240**. The processing chamber **200** may receive a linear array of substrates **240** through apertures **203** in the sides of the processing chamber **200**. The processing chamber **200** includes one or more electrode assemblies **216** configured to provide an electric field to the substrates **240** as the substrates **240** are being processed in the processing chamber **200** for the post-exposure bake process. The processing chamber **200** also includes a heating mechanism (discussed below) to apply heat to the substrate **240** while the electric field is applied for the post-exposure bake process.

The electrode assembly **216** includes at least a first electrode **258** and a second electrode **260**. In some embodiments the electrode assembly **216** is coupled to one or more walls **202** by a fixed stem (not shown). As shown, the first electrode **258** is coupled to a power source **270**, and the second electrode **260** is coupled to a power supply **275**. Electrode assemblies **216** are provided both above the belt **213** and below the belt **213** (and thus both above and below substrates **240** provided on the belt) in order to provide a desired electric field configuration. The specific configuration of the electrode assembly **216** is discussed in further detail below with respect to FIGS. **3**A-**3**F and **5**.

The substrate **240** is electrically floating. Thus, the substrate **240** is not electrically coupled to any conductive elements of the processing chamber **200** or to a ground. The processing chamber **200** may include one or more features to electrically float the substrate **240**. In one example, the belt **213** has an electrically insulating material disposed on a top surface of the belt **213**. The substrate **240** is placed on the electrically insulating material on the belt **213** in order to electrically insulate and float the substrate **240** placed on top of the belt **213**. In another example, the substrate **240** is disposed on the belt, which is electrically isolated from other components of the processing chamber **200**. In yet another example, the processing chamber **200** includes an arm or other mechanism upon which the substrate **240** is disposed. The arm or other mechanism is electrically floating. Electrically floating the substrate **240** helps to shape the electrical field applied by electrode assembly **216** into a desired

configuration. More specifically, electrically floating the substrate **240** helps to shape an electric field into a configuration in which the electric field lines remain substantially parallel to the top (and/or bottom) surface of the substrate **240**, which surface is generally parallel to the surface of the belt **213**.

The processing chamber **200** may include one or more heating sources (also referred to herein as "heating mechanisms") to provide heat to the photoresist layer **250** during the post-exposure bake process. One example of the heating mechanism includes one or more heat lamps positioned within or outside the processing chamber **200**. In another example of the heating mechanism, one or more lasers may be used to heat a photoresist layer **250** (or other layer) positioned on the substrate **240**. In a further example of the heating mechanism, the supply source **204** may be configured to provide heated gas to the processing chamber **200** in order to heat the photoresist layer **250**. In yet another example of the heating mechanism, a microwave heater may be used to heat a photoresist layer **250**. In still another example of the heating mechanism, instead of using a belt **213**, the substrate **240** may instead be supported by an arm that is heated and thus conductively transfers that heat to the photoresist layer **250**. In such embodiments, the arm may be electrically floating or a surface of the arm that supports the substrate **240** may include an electrically insulating layer to cause the substrate **240** to be electrically floating.

Together, the configuration of the electrode assemblies **216** and the fact that the substrate **240** is electrically floating helps to generate a desired electric field configuration. More specifically, the electrode assembly **216** is configured to generate an electric field parallel to the x-y plane defined by the surface of the belt **213**. The electrical floating of the substrate **240** helps to cause the electric field to be substantially parallel to the surface of the substrate **240** along a substantially large portion of the substrate **240**. Moving the substrate **240** via the belt **213** through the processing chamber while the electric field and heat is applied helps to cause the charged species **355** (shown in FIG. **3**A) to move in a desired direction, allowing the interfaces defined by the latent image to be smoother than if no electric field were applied. These charged species may represent the acids described above that are present in the photoresist layer. These acids may be charged, and thus an electric field may affect motion of these charged species **355**.

When applying the electric field and heating the substrate **240**, the processing chamber **200** may be filled with a non-reactive gas or with a vacuum during the post-exposure bake process. The processing chamber **200** is enclosed by a set of walls **202**. The walls **202** generally comprise a material that can structurally support the loads applied by the external environment, which is external to the processing region **206**, when the processing region **206** is heated to a desirable temperature and pumped to a vacuum pressure by a vacuum pump **242** or filled with any desirable gas. The walls **202** may thus comprise a material such as an aluminum material or stainless steel.

The apertures **203** may be sealed with a sealing mechanism, such as a slideable panel, when the post-exposure bake process is performed to allow a vacuum to be generated in the interior of the processing chamber **200**. A vacuum port **214** may be present in any of the walls **202** (e.g., front, back, top, bottom, left, right) to allow a vacuum pump **242** to pull vacuum via valve **219**. The vacuum pump **242** may reduce the pressure of within the processing chamber **200** and exhaust any gases and/or process by-products out of the processing chamber **200**. Gas inlets **217** allow a supply source **204** to provide gases to the interior of the processing chamber **200**.

In the configuration shown in FIG. **2**, the substrate automation system **215** comprises a conveyor **221** that is adapted to support and guide substrates **240** through the processing chamber **200** by use of one or more actuators (not shown), for example, a stepper motor or servo motor. In one configuration, the conveyor **221** comprises two or more rollers **212** and a belt **213** that are configured to support and move the substrates **240** through the processing chamber **200**. In various embodiments, the processing chamber **200** may comprise different types of processing chambers. For example, instead of a processing chamber with conveyor belt, the processing chamber **200** may be an independent processing chamber. Alternatively, the processing chamber **200** may be part of a processing system, such as, for example, an in-line processing system, a cluster processing system, or the track processing system as desired.

The power source **270** and the power supply **275** may have various characteristics in order to provide the electric field described above. For example, the power source **270** and the power supply **275** may be configured to supply between about 500 V and about 100 kV to the electrode assembly **216**, to generate an electric field having a strength between about 0.1 MV/m and about 100 MV/m. In some embodiments, either or both of the power source **270** or the power supply **275** are a pulsed direct current (DC) power supply. The pulsed DC wave may be from a half-wave rectifier or a full-wave rectifier. The DC power may have a frequency of between about 10 Hz and 1 MHz. The duty cycle of the pulsed DC power may be from between about 5% and about 95%, such as between about 20% and about 60%. In some embodiments, the duty cycle of the pulsed DC power may be between about 20% and about 40%. In other embodiments, the duty cycle of the pulsed DC power may be about 60%. The rise and fall time of the pulsed DC power may be between about 1 ns and about 1000 ns, such as between about 10 ns and about 500 ns. In other embodiments, the rise and fall time of the pulsed DC power may be between about 10 ns and about 100 ns. In some embodiments, the rise and fall time of the pulsed DC power may be about 500 ns. In some embodiments, either or both of the power source **270** and the power supply **275** are an alternating current power supply. The waveform applied by such an alternating current power supply may be a sinusoidal waveform. The frequency of such a sinusoidal waveform may be from between 1 Hz to 1 KHz, although the frequency is not limited to those numbers. This AC waveform may be combined with a pulse, as well. In other embodiments, either or both of the power source **270** and the power supply **275** are a direct current power supply. In some embodiments, either or both of the power source **270** and the power supply **275** may use a DC offset. The DC offset may be, for example, between about 0% and about 75% of the applied voltage, such as between about 5% and about 60% of the applied voltage.

FIG. **3**A is a side view of pairs of antennas **320**, **321** above and below a substrate **240** that includes a photoresist layer **250** (shown in FIG. **2**). Electrode assembly **216** (FIG. **2**), which are present above and below substrate **240**, include the antennas **320**, **321** illustrated in FIG. **3**A. The antennas **320**, **321** are configured to provide an electric field to the photoresist layer **250** as described above. FIG. **3**A shows an example configuration of the electric field that is produced by the antennas **320**, **321**.

As shown, an antenna **320(1)** having a positive voltage is present in the space above the substrate **240** and an antenna **320(2)** having substantially the same voltage as the antenna **320(1)** is present in the space below the substrate. Antenna **320(1)** is spaced apart from antenna **320(2)** by distance d_1. Also, an antenna **321(1)** is present above the substrate **240** and is spaced apart from antenna **320(1)** by distance d_2. Antenna **321(2)** is present below the substrate **240** and is spaced apart from antenna **321(2)** by d_1 and from antenna **320(2)** by d_2. Antenna **321(1)** and antenna **321(2)** have a negative voltage as compared with antenna **320(1)** and **320(2)**. Antenna **321(1)** and antenna **321(2)** have substantially the same voltage. This configuration, in which two vertically aligned, "positive" antennas and two vertically aligned, "negative" antennas are present above and below the photoresist **250**, forms an electric field with desirable characteristics, in which the electric field is parallel to the surface of the photoresist **250**.

When the substrate **240**, with photoresist **250**, is heated in the presence of an electric field generated by the antennas **320**, **321** present both above and below the substrate **240**, as shown in FIGS. **2** and **3**A, a uniformity of directional movement is applied to the charged species **355**. The uniform directional movement of the charged species **355** is shown by the double headed arrow **370** in FIG. **3**. In contrast, when the above technique is not utilized, the charged species **355** and polarized species may move randomly, as shown by the arrows **370'**.

For clarity, in FIG. **3**A, only two pairs of antennas **320**, **321** are shown. However, those of skill in the art will understand that additional antennas **320**, **321** may be present in processing chamber as well. For example, additional antennas **320**, **321** in horizontal alignment may be present, as illustrated in FIG. **3**C. Additionally, additional stacked antennas **320**, **321** in vertical alignment may be present, as illustrated in FIG. **3**B.

FIG. **3**B is a side view of a series of antennas **320**, **321** arranged in a stacked configuration. In order to support additional processing throughput, the electrode assemblies **216** of FIG. **2** can be stacked. A substrate **240** with photoresist layer **250** may be disposed between each pair of antenna **320** and antenna **321** and may be scanned in a horizontal direction while heated in order to perform the post-exposure bake procedure described above. The configuration of the electric field is substantially the same for each substrate **240** as described above with respect to FIG. **3**A.

FIG. **3**C is a top-down view of the electrode assembly **216** that include the antennas **320**, **321**, according to an example. While a specific configuration of electrode assembly **216** that includes antennas **320**, **321** is illustrated in FIG. **3**C, those of skill in the art will understand that other configurations including antennas **320**, **321** configured as shown in FIG. **3**A are possible as well.

The electrode assembly **216** shown in FIG. **3**C includes at least the first electrode **258** and the second electrode **260**. The first electrode **258** includes a first terminal **310**, a first support structure **330**, and one or more antennas **320**. The second electrode **260** includes a second terminal **311**, a second support structure **331**, and one or more antennas **321**. The first terminal **310**, the first support structure **330**, and the one or more antennas **320** of the first electrode **258** may form a unitary body. Alternatively, the first electrode **258** may include separate portions that may be coupled together. For example, the one or more antennas **320** may be detachable from the first support structure **330**. The second electrode **260** may similarly be a unitary body or be comprised of separate detachable components. The first electrode **258** and the second electrode **260** may be prepared by any suitable means. For example, the first electrode **258** and the second electrode **260** may be fabricated by machining, casting, or additive manufacturing.

The first support structure **330** may be made from a conductive material, such as metal. For example, the first support structure **330** may be made of silicon, polysilicon, silicon carbide, molybdenum, aluminum, copper, graphite, silver, platinum, gold, palladium, zinc, other materials, or mixtures thereof. The first support structure **330** may have any desired dimensions. For example, the length L of the first support structure **330** may be between about 25 mm and about 450 mm, for example, between about 100 mm and about 300 mm. In some embodiments, the first support structure **330** has a length L approximately equal to a diameter of a standard semiconductor substrate. In other embodiments, the first support structure **330** has a length L that is larger or smaller than the diameter of a standard semiconductor substrate. For example, in different representative embodiments, the length L of the first support structure **330** may be about 25 mm, about 51 mm, about 76 mm, about 100 mm, about 150 mm, about 200 mm, about 300 mm, or about 450 mm. The width W of the first support structure **330** may be between about 2 mm and about 25 mm. In other embodiments, the width W of the first support structure **330** is less than about 2 mm. In other embodiments, the width W of the first support structure **330** is greater than about 25 mm. The thickness of the first support structure **330** may be between about 1 mm and about 10 mm, such as between about 2 mm and about 8 mm, such as about 5 mm. In some embodiments, the first support structure **330** may be square, cylindrical, rectangular, oval, rods, or other shapes. Embodiments having round exterior surfaces may avoid arcing.

The support structure **330** may be made of the same materials as the second support structure **331**. The range of dimensions suitable for the first support structure **330** is also suitable for the second support structure **331**. In some embodiments, the first support structure **330** and the second support structure **331** are made of the same material. In other embodiments, the first support structure **330** and the second support structure **331** are made of different materials. The lengths L, widths W, and thicknesses of the first support structure **330** and the second support structure **331** may be the same or different.

The one or more antennas **320** of the first electrode **258** may also be made from a conductive material. The one or more antennas **320** may be made from the same materials as the first support structure **330**. The one or more antennas **320** of the first electrode **258** may have any desired dimensions. For example, a length L**1** of the one or more antennas **320** may be between about 25 mm and about 450 mm, for example, between about 100 mm and about 300 mm. In some embodiments, the first support structure **330** has a length L**1** approximately equal to the diameter of a standard substrate. In other embodiments, the length L**1** of the one or more antennas **320** may be between about 75% and 90% of the diameter of a standard substrate. A width W**1** of the one or more antennas **320** may be between about 2 mm and about 25 mm. In other embodiments, the width W**1** of the one or more antennas **320** is less than about 2 mm. In other embodiments, the width W**1** of the one or more antennas **320** is greater than about 25 mm. The thickness of the one or more antennas **320** may be between about 1 mm and about 10 mm, such as between about 2 mm and about 8 mm. The one or more antennas **320** may have a cross-section that is

square, rectangular, oval, circular, cylindrical, or another shape. Embodiments having round exterior surfaces may avoid arcing.

Each of the antennas **320** may have the same dimensions. Alternatively, some of the one or more antennas **320** may have different dimensions than one or more of the other antennas **320**. For example, some of the one or more antennas **320** may have different lengths L**1** than one or more of the other antennas **320**. Each of the one or more antennas **320** may be made of the same material. In other embodiments, some of the antennas **320** may be made of a different material than other antennas **320**.

The antennas **321** may be made of the same range of materials as the antennas **320**. The range of dimensions suitable for the antennas **320** is also suitable for the antennas **321**. In some embodiments, the antennas **320** and the antennas **321** are made of the same material. In other embodiments, the antennas **320** and the antennas **321** are made of different materials. The lengths L**1**, widths W**1**, and thicknesses of the antennas **320** and the antennas **321** may be the same or different.

The antennas **320** may include between 1 and about 40 antennas **320**. For example, the antennas **320** may include between about 4 and about 40 antennas **320**, such as between about 10 and about 20 antennas **320**. In other embodiments, the antennas **320** may include more than 40 antennas **320**. In some embodiments, each of the antennas **320** may be substantially perpendicular to the first support structure **330**. For example, in embodiments where the first support structure **330** is straight, each antenna **320** may be substantially parallel to the first support structure **330**. Each of the antennas **320** may be substantially parallel to each of the other antennas **320**. Each of the antennas **321** may be similarly positioned with respect to the support structure **331** and each other antenna **321**.

Each of the antennas **320** has a terminal end **323**. Each of the antennas **321** has a terminal end **325**. A distance C is defined between the first support structure **330** and the terminal end **325**. A distance C' is defined between the second support structure **331** and the terminal end **323**. Each of the distances C and C' may be between about 1 mm and about 10 mm. In other embodiments, the distances C and C' may be less than about 1 mm or greater than about 10 mm. In some embodiments, the distance C and the distance C' are equal. In other embodiments, the distance C and the distance C' are different.

A distance A is defined between facing surfaces of one of the antennas **321** and an adjacent one of the antennas **321**. The distance A' is defined between facing surfaces of one antenna **320** and an adjacent one the antennas **320**. The distances A and A' may be greater than about 6 mm. For example, the distances A and A' may be between about 6 mm and about 20 mm, such as between about 10 mm and about 15 mm. The distances A and A' between each adjacent antennas **321**, **320** may be the same or different. For example, the distances A' between the first and second, second and third, and third and fourth antennas of the one or more antennas **320** may be different. In other embodiments, the distances A' may be the same.

A distance B is defined between facing surfaces of one of the antennas **320** and an adjacent one of the antennas **321**. The distance B may be, for example, greater than about 1 mm. For example, the distance B may be between about 2 mm and about 10 mm, such as between about 4 mm and about 6 mm. The distance B defined between may be the same, each distance B may be different, or some distances B may be the same and some distances B may be different. Modifying the distance B allows for easy control of the electric field strength.

The antennas **320**, **321** may be oriented in an alternating arrangement above the photoresist layer **250** and below. For example, the antennas **320** of the first electrode **258** and the antennas **321** of the second electrode **260** may be positioned such that at least one of the antennas **320** is positioned between two of the antennas **321**. Additionally, at least one antenna **321** may be positioned between two of the antennas **320**. In some embodiments, all but one of the antennas **320** is positioned between two of the antennas **321**. In those embodiments, all but one of the antennas **321** may be positioned between two of the antennas **320**. In some embodiments, the antennas **320** and the antennas **321** may each have only one antenna.

In some embodiments, the first electrode **258** has a first terminal **310**, and the second electrode **260** has a second terminal **311**. The first terminal **310** may be a contact between the first electrode **258** and the power source **270**, the power supply **275**, or a ground. The second terminal **311** may be a contact between the second electrode **260** and the power source **270**, the power supply **275**, or a ground. The first terminal **310** and the second terminal **311** are shown as being at one end of the first electrode **258** and the second electrode **260**, respectively. In other embodiments, the first terminal **310** and the second terminal **311** may be positioned at other locations on the first electrode **258** and the second electrode, respectively. The first terminal **310** and the second terminal **311** have different shapes and sizes than the first support structure **330** and the support structure **331**, respectively. In other embodiments, the first terminal **310** and the second terminal **311** may have generally the same shapes and sizes as the first support structure **330** and the support structure **331**, respectively.

In operation, a voltage may be supplied from a power supply, such as the power source **270** or the power supply **275**, to the first terminal **310** or the second terminal **311**. The supplied voltage creates an electric field between each antenna of the one or more antennas **320** and each antenna of the one or more antennas **321**. The electric field will be strongest between an antenna of the one or more antennas **320** and an adjacent antenna of the one or more antennas **321**. The interleaved and aligned spatial relationship of the antennas **320**, **321** produces an electric field predominantly in a direction parallel to the plane defined by the surface of the belt **213**. The substrate **240** is positioned on the belt **213** such that the latent image lines **255** are parallel to the electric field lines generated by the electrode assembly **216**. Since the charged species **355** are charged, the charged species **355** are affected by the electric field. The electric field drives the charged species **355** generated by the photoacid generators in the photoresist layer **250** in the direction of the electric field. By driving the charged species **355** in a direction parallel with the latent image lines **255**, line edge roughness may be reduced. The uniform directional movement is shown by the double headed arrow **370**. In contrast, when a voltage is not applied to the first terminal **310** or the second terminal **311**, an electric field is not created to drive the charged species **355** in any particular direction. As a result, the charged species **355** may move randomly, as shown by the arrows **370'**, which results in increased line edge roughness.

FIG. **3D** is a side view of a configuration for a holder **380** for holding the substrate **240**, according to an example. Without holder **380**, the outer edge **384** of the substrate **240** and layers applied on top of the substrate act as a boundary

between materials with differing dielectric constants (e.g., the material of the substrate **240** and layers as opposed to air, vacuum, or other gas within processing chamber **200**). These differing dielectric constants may cause the electric field near the edge of the substrate **240** to be distorted. A holder **380** is therefore placed under substrate **240** in order to prevent field distortion. The holder **380** is generally of a material that has a similar dielectric constant to the material of the substrate **240** and layers above the substrate. One example of such a material is quartz. The holder **380** is also configured such that the area surrounding the substrate **240** and other layers has a dielectric constant that is similar to the dielectric constant of the substrate and other layers. Thus, the holder **380** may be configured such that walls **383** of the holder sound the entire height of the substrate **240** and layers above the substrate. A bottom portion **382** of the holder **380** may include a cut-out portion indicated with dotted-lines (i.e., in some embodiments, cutout portion **382** may be absent from holder **380**). The uniformity of dielectric constant reduces the amount of distortion experienced by the substrate **240** and layers above. FIG. **3**E illustrates an example of a holder **380** that has a square shape and FIG. **3**F illustrates an example holder that has a ring shape with a central cutout portion **382**.

FIG. **4**A depicts a photoresist layer **404** disposed on a material layer **402** formed on a substrate **400** during a lithography exposure process. As discussed above, an electric field from the electrode assembly **216** is applied during a post exposure baking process. During the lithographic exposure process, radiation **412** is directed to a first region **408** of the photoresist layer **404** while with a second region **406** of the photoresist layer **404** protected by a photomask **410**. Photoacid, shown as e^- in FIG. **4**A, is generated in the exposed first region **408** in the photoresist layer **404** when photoacid generator (PAG) is exposed to the radiation **412**, such as a ultraviolet (UV) radiation. Although FIG. **4**A illustrates the photoacid with an "e^-" symbol, this is not specifically reflective of the actual charge of photoacid compounds—but of the fact that photoacide compounds generally are electrically charged.

In a conventional process, photoacid is primarily generated in the exposed first region **408** of the photoresist layer **404** during the light exposure process. During the post-exposure bake period, movement of photoacid is generally random and the interface between areas within the photoresist layer **404** that include the generated photoacid and areas that do not include the generated photoacid may comprise an unclear boundary (i.e., interface **430**). For example, the random movement may result in at least a portion of the photoacid diffusing into the second region **406**, as shown in the arrow **422**. Such photoacid drift may result in line edge roughness, resolution loss, photoresist footing, and profile deformation, which may cause inaccurate transfer of features to the underlying material layer **402**. This inaccurate transfer of features could lead to device failure.

By applying the electric field described above to the photoresist layer **404** during the post-exposure bake process, distribution of photoacid in the exposed first region **408** may be efficiently controlled and confined. The electric field as applied to the photoresist layer **404** may move photoacid in vertical directions (e.g., the y-direction shown by arrows **416** and **420**, which is substantially perpendicular to the planar surface of the substrate **400**) with minimal lateral motion (e.g., x direction shown by the arrow **422**). (Note that for completeness, direction **414** and associated direction **428** are shown). That is, the photoacid generally does not diffuse into the adjacent second region **406**. Generally, photoacid has a certain polarity that may be affected by an electric field applied thereto. Such an applied electric field will orient photoacid molecules in directions that are in accordance with the electric field. When such electric field is applied, the photoacid moves in a desired direction such that the photoacid generally does not cross into the second region **406**.

FIG. **4**B depicts a top view of the photoresist layer **404** including a portion of the first region **408** and the second region **406** delineated by the interface **430**. After the electric and/or magnetic field is applied to the photoresist layer **450**, distribution of photoacid **450** is generally constrained to the first region **408** without diffusing cross to the second region **406**. Thus, by applying the electric field and/or magnetic field as described above, a clearly defined interface **430** may be obtained, thus forming a patterned photoresist layer with a sharp profile, a high resolution and reduced line edge roughness and defects.

FIG. **5** depicts a flow diagram of a method **500** for controlling photoacid distribution/diffusion in a photoresist layer during a lithographic exposure process or during a prebaking process or a post-baking process. The method **500** begins at block **502** by positioning a substrate, such as the substrate **400** described above, into a processing chamber, such as the processing chamber **200** depicted in FIG. **2**, with an electrode assembly and a magnetic assembly disposed therein. At block **504**, after the substrate **400** is positioned in place, an electric field is applied to the processing chamber to control photoacid movement that occurrs in a photoresist layer disposed on the substrate. At block **506**, after the electric field is applied to the photoresist layer disposed on the substrate, photoacid as generated may be moved primarily in a single plane, so as to reduce likelihood of photoacid diffusing into a region in which photoacid is not intended to be included. By utilizing directional control of photoacid distribution, a photoresist layer with a well-defined edge profile, having substantially no blurring, having high resolution, and having reduced line edge roughness may be obtained.

Although described above in the context of improving line edge roughness and line edge width, the techniques provided above may additionally be used to improve the sensitivity of photoresist. This sensitivity is associated with the reaction that makes the photoresist soluble. By applying the electromagnetic field techniques described above, the reaction that causes the photoresist to become soluble is sped up, which improves the sensitivity.

The previously described embodiments have many advantages, including the following. For example, the embodiments disclosed herein may reduce or eliminate line edge/width roughness with high resolution and sharp edge profile. The aforementioned advantages are illustrative and not limiting. It is not necessary for all embodiments to have all the advantages.

While the foregoing is directed to embodiments of the present disclosure, other and further embodiments of the disclosure may be devised without departing from the basic scope thereof, and the scope thereof is determined by the claims that follow.

What is claimed is:

1. A method of processing a substrate, the method comprising:

applying a photoresist layer comprising a photoacid generator to a substrate, wherein a first portion of the photoresist layer has been exposed unprotected by a photomask to a radiation light in a lithographic exposure process; and

applying an electric field to alter movement of photoacid generated from the photoacid generator substantially in a vertical direction, wherein the electric field is applied by a first alternating pair of a positive voltage electrode and a negative voltage electrode and a second alternating pair of a positive voltage electrode and a negative voltage electrode, and wherein applying the electric field further comprises:

charging a first antenna with a first voltage and a second antenna with a second voltage, the first antenna and the second antenna being disposed above the photoresist layer, and the first and the second voltages having opposite polarities; and

charging a third antenna with a third voltage and a fourth antenna with a fourth voltage, the third antenna and the fourth antenna being disposed below the photoresist layer, and the third and the fourth voltages having opposite polarities.

2. The method of claim **1**, further comprising:

electrically floating the substrate.

3. The method of claim **1**, wherein the electric field is applied to the photoresist layer during a post-exposure bake process performed after the lithographic exposure process.

4. The method of claim **1**, wherein applying the electric field further comprises:

controlling photoacid generated in the first portion of the photoresist layer in a longitudinal direction defined in a plane interfaced with a second portion of the photoresist layer protected by the photomask during the lithographic exposure process.

5. The method of claim **1** further comprising:

moving the substrate via a conveyor.

6. The method of claim **1**, wherein the first voltage and the second voltage each comprises one of a direct current voltage, an alternating current voltage, or a pulse.

7. The method of claim **1** further comprising:

heating the photoresist layer.

8. The method of claim **1** further comprising:

placing the substrate in a holder with walls having a substantially similar dielectric constant to a dielectric constant of the substrate.

9. A processing chamber for processing a substrate, the processing chamber comprising:

a supporting assembly with a surface for supporting a substrate;

a first electrode assembly comprising a first antenna and a second antenna positioned above the surface of the supporting assembly;

a second electrode assembly comprising a third antenna and a fourth antenna positioned below the surface of the supporting assembly;

a first power source coupled to the first electrode assembly and configured to provide the first antenna with a first voltage and the second antenna with a second voltage, the first and second voltages having opposite polarities; and

a second power source coupled to the second electrode assembly and configured to provide the third antenna with a third voltage and the fourth antenna with a fourth voltage, the third and fourth voltages having opposite polarities.

10. The processing chamber of claim **9**, further comprising:

an insulating layer disposed on the supporting assembly for electrically floating the substrate.

11. The processing chamber of claim **9**, wherein first power source and second power source are configured to provide the positive voltage and negative voltage during a post-exposure bake process performed after the lithographic exposure process.

12. The processing chamber of claim **9**, wherein the supporting assembly comprises a conveyor operable to position a substrate relative to the first antenna, the second antenna, the third antenna, and the fourth antenna.

13. The processing chamber of claim **9** further comprising:

a heating mechanism for applying heat to the photoresist layer.

14. The processing chamber of claim **9** further comprising:

a holder configured to support the substrate, wherein the holder has walls, the walls having a substantially similar dielectric constant to a dielectric constant of the substrate.

15. The processing chamber of claim **9**, wherein the first antenna and the second antenna are interleaved, and the third antenna and the fourth antenna are interleaved.
